Bridge – Products, Factors, and Factor Pairs

Name:_

In mathematics, **factors** are numbers that create new numbers when they are multiplied. A number resulting from multiplication is called a **product**. In other words, since 2(3) = 6, 2 and 3 are **factors** of 6, while 6 is the **product** of 2 and 3. Also, 1(6) = 6, so 1 and 6 are two more factors of 6. Thus, the number 6 has four factors; 1,2,3, and 6. In this lesson, you will use an extended multiplication table to discover some interesting patterns of numbers and their factors.

1-73.

Have you ever noticed how many patterns exist in a simple multiplication table? Such a table is a great tool for exploring products and their factors. Fill in the missing products, without the use of a calculator.

											********				********
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
1	1	2	3	4	5	6	7	8	9		11	12	13	14	15
2	2	4	6	8	10	12	14	16	18		22	24	26	28	30
3	3	6	9	12	15	18	21	24	27		33	36	39	42	45
4	4	8	12	16	20	24	28	32	36		44	48	52	56	60
5	5	10	15	20	25	30	35	40	45		55	60	65	70	75
6	6	12	18	24	30	36	42	48	54		66	72	78	84	90

15	15	30	45	60	75	90	103	120	זכו		163	120	167	210	222

1-74.

Gloria was looking at the multiplication table and noticed an interesting pattern.

"Look," she said to her team. "All of the prime numbers show up only two times as products in the table, and they are always on the edges."

Discuss Gloria's observation with your team. Then choose one color to mark all of the prime numbers. Why does the placement of the prime numbers make sense?

1-76.

Consider the number 36, which could have been Ann's number in part (b) of problem 1-62.

- a. Choose a color or design (such as circling or drawing an X) and mark every 36 that appears in the table.
- b. Imagine that more rows and columns are added to the multiplication table until it is as big as your classroom floor. Would 36 appear more times in this larger table? If so, how many more times and where? If not, how can you be sure?
- c. List all of the **factor pairs** of 36. (A **factor pair** is a pair of numbers that multiply to give a particular product. For example, 2 and 10 make up a factor pair of 20, because $2 \cdot 10=20$.) How do the factor pairs of 36 relate to where it is found in the table? What does each factor pair tell you about the possible rectangular arrays for 36? How many factors does 36 have?

Bridge – Products, Factors, and Factor Pairs **1-77.**

Frequency is the number of times an item appears in a set of data. What does the frequency of a number in the multiplication table tell you about the rectangular arrays that are possible for that number?

- a. Gloria noticed that the number 12 appears, as a product, 6 times in the table. She wonders, "*Shouldn't there be 6 different rectangular arrays for 12?*" What do you think? Work with your team to draw all of the different rectangular arrays for 12. Explain how they relate to the table.
- b. How many different rectangular arrays can be drawn to represent the number 48? How many times would 48 appear as a product in a table as big as the classroom? Is there a relationship between these answers?
- c. In problem 1-76 how many different rectangular arrays could be drawn to represent the number 36? How many times did it appear as a product in a table as big as the room?

Does the pattern you noticed for 12 and 48 apply to 36? If so, why does this make sense? If not, why is 36 different?

1-78. PRIME FACTORIZATION

- a. What are all the factors of 200?
- b. A **prime factor** is a factor that is also a prime number. What are the prime factors of 200?

c.	Writing a number as a product of only prime numbers is called prime	200			
	numbers. She shared with her team the beginning of her work, which is	= 4 · 50			
	shown at right.	$= 2 \cdot 2 \cdot 10 \cdot 5$			
	Notice that Tatiana uses a "dot" (\cdot) to represent multiplication. This is	$= 2 \cdot 2 \cdot 5 \cdot 2 \cdot 5$			

a way to show multiplication without using an "x". Try to use this method now so that when you learn algebra, you are not confused about the use of the letter x as a variable. What process do you think was going through Tatiana's mind when she wrote 200 as a product of prime factors?

Name:

Bridge – Products, Factors, and Factor Pairs

d. Do you think it matters what products Tatiana wrote in her second step? What if she wrote 10.20 instead? Finish this **prime factorization** using Tatiana's process.

200

$= 10 \cdot 20$

1-79.

Write the prime factorization of each of the numbers below.

a.	100	b.	36	с.	54	d.	600
----	-----	----	----	----	----	----	-----

1-80.

When you write a number as a product of prime factors, often you have many factors to record. Explore this idea further in parts (a) through (c) below.

- a. How many prime factors did you need to represent part (d) of problem 1-79?
- b. To make it easier to record prime factors, you can use exponents.

Do you remember how repeated addition can be written in shorter form using multiplication? For example, 10+10+10+10+10 can be written as $5\cdot10$. Similarly, repeated multiplication can be written in shorter form using exponents: $10\cdot10\cdot10\cdot10=105$.

The prime factorization of 200 from problem 1-78 was $2 \cdot 2 \cdot 2 \cdot 5 \cdot 5$. How could you write this with exponents?

c. Write your answers from problem 1-79 in exponent form.

Name:

Reflection

1. What steps did you take today to help figure out the factorization of numbers? Write at least two sentences and add **symbols and drawings** to help explain.

2. In terms of operators, addition is repeated counting. Multiplication is repeated addition. An exponent is repeated multiplication. When we simplify expressions, we start with the most powerful operations first, such as exponents, then work our way to less powerful operations. Simplify the expression below by first doing the exponents, then the multiplication, then addition. Show all your steps.

$$2^3 + 4(5)$$

- 3. What questions can you ask about today's work to help extend your learning? Think about how exponents and multiplication work in tandem.
- 4. Using the digits from 0-9 without repeating, write a number whose last place value is the thousandths place.
- 5. Using the digits from 0-9 without repeating, write a number whose last place value is the hundredths place and would be rounded UP at the tenths place
